1. Introduction

In this document I will explain the decisions I have made for my project based on the research I have done. I will explain the architecture of my application.

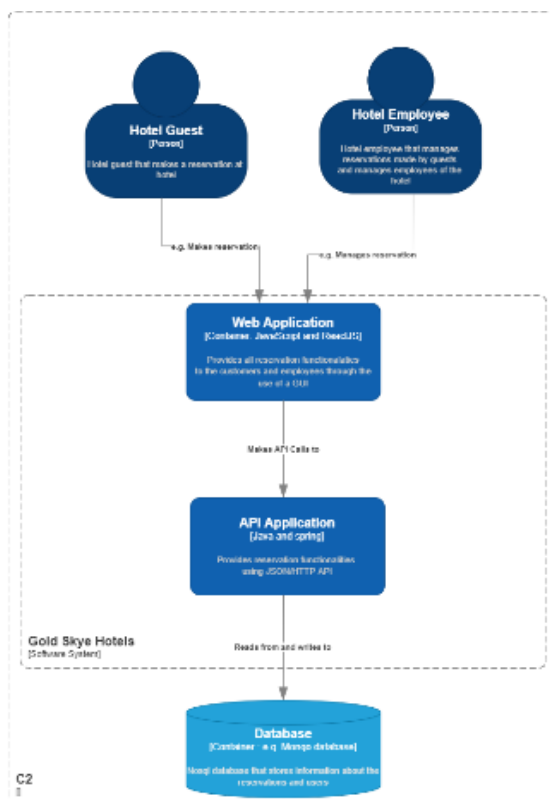

2. Architecture

2.1 C4 Diagram

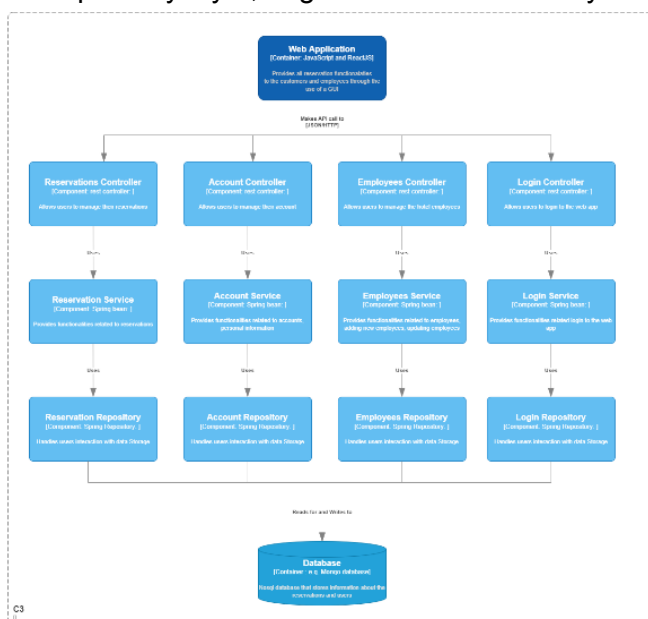

C1: There are two types of users for my application, the guests of the hotel who can manage their bookings and the employees who work at the hotel, who can manage their daily work tasks.

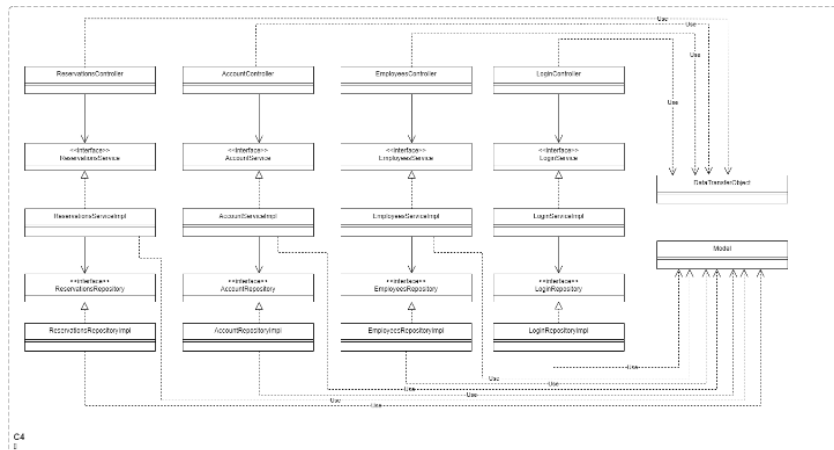

C2: The system is divided in two parts, the web application that is built using the front end JavaScript library React and the backend Java APIs.

C3: For now, the API is divided into 4 sections, a section for reservations, accounts, employees and login. These 4 sections are separated into 3 layers, the Controller, Service and Repository layer, to guarantee the three layer design.

C4: This is the first version of the UML. All three layers are connected to each other and separated by interfaces.

2.2 How is SOLID guaranteed

The solid principles are used in Object Oriented Design, to help create a design that is easily maintainable and extendable.

- Single Responsibility:**
 Every single class created is responsible for only one task. This is possible by dividing the controllers by feature, so there are no controllers responsible for example both the employees and the reservations at the same time.
- Open/Closed Principle:**
 To keep the code extendable, the open/closed principle is used. Using interfaces will help with this, because this means you don't have to change the existing code if you want to add a new feature. The objects are open for extension but closed for modification. An example for this in my application is the payment method. If the company decides to add another payment method, they can add it without having to modify the current payment methods.
- Liskov substitution:**
 The liskov substitution means that every subclass should be able to be substituted by the base class. For my application I use inheritance in the Person class. The person class is the main class and Guest and Employee are subclasses. For the different Employee types I will add more subclasses in the future, to separate the functionalities.
- Interface Segregation Principle:**
 I will create multiple interfaces to segregate functionalities between users, so that for

example a front desk employee doesn't have access to the statistics meant for the manager.

- **Dependency Inversion Principle:**

The layers are separated by interfaces, the classes depend on the interfaces and are given them when created. For example if you want to switch between using a fake database and a real database you can give the class another instance of the database, without getting any errors or having to modify the existing code.

3. Applied Research

Here you can find my research questions for my project. The actual research will be done in sprint 3.

3.1 What is a good front end library or framework for my application?

dsfdsf

3.2 What database should I use?

dfsdfsd

3.3 How should I store my user data?

dsfkdsj

3.4 How should I store the data for the reservations?

jhfjsdhfj

3.5 What type of Authentication and Authorisation should I use?

dsklfjdsIf

3.6 What is Spring Boot?

fdlkjfsd

3.7 Should I use Maven or Gradle for my project?

sdsdfd

3.8 What is a good backend for OOD?

dfsd
